CareSooner ? Early Health Concern Explainer

DSH Hacks V2 ? AI x Healthcare | By Umar Shareef (solo) | General information only ? not a diagnosis

Problem

When a health concern appears, people often do not know what to notice, what counts as urgent, or what to ask a clinician. That confusion delays care, and a first appointment is often spent trying to describe a pattern from memory instead of discussing it.

Solution

CareSooner is a web app that turns a confusing concern into plain-language general information in four steps: (1) choose up to three concern topics; (2) run a red-flag safety check, shown first if any red flag applies; (3) track dated observations in the browser to spot a repeating or worsening pattern early; (4) generate a printable visit-prep note with questions for a clinician.

How it works ? and why it is honest

The engine is a transparent rule set (rules R1-R6, shown in the app). No machine-learning model, no external API, no black-box score. Red flags always come first. The app never names a cause, never predicts a disease, and never says what a user has. Every result carries the same disclaimer, and the tracker stores data only in the visitor’s own browser; the server is stateless and stores nothing.

What was built

A working prototype: Python standard library server, plain HTML/CSS/JavaScript front end, eight concern topics, a ten-item red-flag check, a browser-only change tracker, and a visit-note generator. Tests cover the safety rules, including red-flag priority, invalid inputs, and a ban on diagnosis wording in all output.

Limits and next steps

Limits: general information only; not validated on patients or medical records; English only for now. Next: clinician review of the information text, more languages, and accessibility testing with real users ? before any claim beyond general information is ever made.

Built with

Python (standard library only), HTML, CSS, JavaScript. No accounts, no database, no API keys.
